Abstract

The leafhopper *Poekilloptera phalaenoides* L. (Auchenorrhyncha: Flatidae) is a very important species in agriculture because it causes damages and economic losses in agricultural activities. In observing fragments of semi-deciduous forest, riparian forest and cerrado forest (Cerradão) in Jataí, Montividiu and Paraúna in the southwest of the state of Goiás during the month of January 2012, were observed natural populations of *Tachigali vulgaris* (carvoeiro-branco). In the southwest of Goiás, an important agricultural region of the country, little is known about the damage caused to commercial crops by the leafhopper treated in this work, but here we call attention to the action of an agricultural pest interacting negatively with the native vegetation. The presence of *P. phalaenoides* in the Cerrado is already known, but the presence of the spittlebug in the southwest of the state of Goiás in *T. vulgaris*, especially in a situation of damage to the native population of the tree in forest fragments surrounded by agricultural crops. Thus, the objective of this work is to bring this first record of *P. phalaenoides* in *T. vulgaris* in the Cerrado of southwestern goiano.

Keywords: leafhopper, Cerrado, phytophagous, honeydew, host

Primeiro registro de *Poekilloptera phalaenoides* encontrados em *Tachigali vulgaris* (Fabaceae: Caesalpinioideae) no sudoeste de Goiás, Brasil

Resumo

A cigarrinha *Poekilloptera phalaenoides* L. (Auchenorrhyncha: Flatidae) é uma conhecida espécie dentre culturas agrícolas e de interesse econômico devido os danos causados em atividades agrícolas. Observando fragmentos de mata estacional semidecidual, mata ciliar e cerradão em Jataí, Montividiu e Paraúna no sudoeste do estado de Goiás, durante o mês de janeiro de 2012, foram observadas populações naturais de *Tachigali vulgaris* (carvoeiro-branco). Em áreas que *P. phalaenoides* reduz o fitness de *T. vulgaris*, o ritmo da sucessão ecológica da área poderá ser modificado dependendo dos níveis da infestação das plantas. A presença de *P. phalaenoides* no Cerrado já é conhecida, mas a presença da cigarrinha no sudoeste do Estado de Goiás em *T. vulgaris*, especialmente em situação de prejuízo a população nativa em fragmentos florestais cercados de culturas agrícolas, é relato científico que torna importante este trabalho. Assim o objetivo deste trabalho é trazer este primeiro registro de *P. phalaenoides* em *T. vulgaris* no Cerrado do sudoeste goiano.

Palavras-chave: Cigarrinha, Cerrado, fitófago, honeydew, hospedeiro

Introduction

P. phalaenoides Linnaeus, 1758 (Auchenorrhyncha: Flatidae) is a very important species in agriculture, because it is a common plague of *Cassia*, *Delonix* (Caesalpiniaceae), *Cajanus*, *Dipterix* (Fabaceae), *Manguifera* (Anacardiaceae), *Annona* (Annonaceae), *Eucalyptus*, *Psidium* (Myrtaceae), *Rosa*, *Prunus* (Rosaceae), *Coffea* (Rubiaceae), *Citrus* (Rutaceae), *Theobroma* (Malvaceae), *Enterolobium*, *Pithecellobium*, *Inga*, *Albizia*, *Acacia* (*A. mangium*) e *Mimosa*

caesalpiniaeefolia (Mimosaceae) (Maes 2004; Querino et al., 2007; Guimarães de Menezes et al, 2012). This species causes big damage, resulting in economic losses (Del-Claro e Oliveira, 1999; Fischer et al., 2005; Styrsky e Eubanks, 2007).

P. phalaenoides is a phytophagous leafhopper and when it is feeding of the host plant, the leafhopper produces the honeydew (a very concentrate sugar), allowing that it continues to absorb more nectar. This honeydew is a stick substance that glues on leaves, branches and even on the ground (Maes, 2004). Querino et al., 2007 suggests that this

substance obstructs the breath, transpiration and photosynthesis process and, probably reducing the vegetative growth, fructification and, consequently, the success of the reproduction process of the plant host (Del-Claro e Oliveira, 1999; Fischer et al., 2005; Styrsky e Eubanks, 2007; Melo et al., 2016).

The presence of *P. phalaenoides* in the Cerrado is already known (Oliveira e Frizzas, 2015), however, the presence of the spittlebug in the southwest of the state of Goiás in *T. vulgaris*, especially in a situation of damage to the native population of the tree in forest fragments surrounded by agricultural crops, was not registered. Thus, the objective of this work is to present the first record of *P. phalaenoides* in *T. vulgaris* in the Cerrado of southwestern Goiânia.

The points were tagged in remnants of the Cerrado phytophysiognomy using the geographical coordinates of the Garmin e-trex GPS. So, in an observation of s Semideciduous Forest, Riparian Forest and Cerradão fragments, at Jataí (n = 5; 17°42'S and 51°30'W), Montividiu (n = 10; 17°05'S and 50°40'W) and Paraúna (n = 10; 17°30'S and 51°18'W), southwest of Goiás, Brazil in 2012, January. For the survey and identification of the botanical species in the marked points, plots of 20x30 m² were marked in each locality. *T. vulgaris* L. G. Silva and H. C. Lima (Fabaceae: Caesalpinoideae) were identified with the help of a botanical identification key (Barroso et al., 1991).

In order to identify the sucking insects, active sampling through the use of entomological net and deadly camera was performed (Silva-Neto et al., 2016). Flat stereomicroscope with a camera lucida attached and photographic cameras were used. In order to identify the species, the entomofauna identification keys (Baptista, 2006; Fujihara et al., 2011) and entomological collections of the Federal University of Goiás were used as reference (Entomological collection of the Laboratory of Plant Reproductive Biology).

Here, we showed the first record of *P. phalaenoides* found on *T. vulgaris* L. G. Silva & H. C. Lima (Fabaceae: Caesalpinoideae) in south-West of Goiás, Brazil. The presence of this leafhopper in species with economic interest is very known, but few observations have been made about native species in natural areas. Natural populations of *T. vulgaris* was observed and all of them presented the leafhopper *P. phalaenoides*.

We observe many individuals of *T. vulgaris* damaged and its branches were senescent when the leafhoppers were there (Figure 1). We also found, above the *T. vulgaris*, leafhopper individuals in a large number (ten or more), in both stages, mature and immature stage. Were also observed populations of ants feeding the honeydew, near the nectar, like they were protecting the leafhoppers (Del-Claro e Oliveira, 1999; Fischer et al., 2005; Styrsky e Eubanks, 2007; Paris e Espadaler, 2009).

T. vulgaris is a pioneer tree, with fast growth, well-known to form forests quickly, shadowing the climax species. In areas that *P. phalaenoides* affect the *T. vulgaris* fitness, the ecologic succession may be changed, depending of the level of infestation (Oliveira e Frizzas, 2015). Furthermore, it's not very known the dynamics of the relationship between *P. phalaenoides* and native species.

Figure 1. *Poekilloptera phalaenoides* L. on the branch of *Tachigali vulgaris* Silva & Lima (left) and the whole plant (right; Foto: Carlos de Melo e Silva Neto).

In the study area, the most common agricultural species are soybean (*Glycine max* L.; Fabaceae), corn (*Zeamays* L.; Poaceae), sorghum (*Sorghum bicolor* L.; Poaceae), sunflower (*Helianthus annuus* L.; Asteraceae), sugar cane (*Saccharum* spp.; Poaceae) and a few plantations of *Eucaliptus* sp. The disequilibrium of native vegetation around cultivated vegetation may increase the population of leafhoppers in native trees. At south-west of Goiás, an important agricultural region of Brazil, a little bit is known about the negative effects of this leafhopper in farms, but we call the attention the action of the negative interaction of *P. phalaenoides* with native forests (Gonçalves et al., 2016). Future studies should be carried out to confirm the relation to the increase of the population of the leafhopper and the reduction of the population of *T. vulgaris*, in addition to the possibility that the insect is also affecting other species.
